Note:

[•] Key ways are British standard metric B.S. 4235: Part 1:1972 and conform to I.S.O recommendations. Where a key is to be used it should be parallel and side fitting with top clearance. Depth of key way is measured at the center.

[•] Taper Bush with Imperial bores can also be supplied.

Pulley balancing

Static Balancing

Concept: When the Pulley is statically balanced, then the center of mass lies on the axis of rotation. **Cross-check:** Rotate the Pulley to any angular position and leave it. If it is statically balanced, then the Pulley will retain its position.

Procedure:

- a) You are provided with 4 different masses (in the from of bars) and thus "the shaft + 4 masses" constitutes your system.
- b) As of now you assume that the center of mass of the bars is at equidistant from the axis of rotation.

- c) Orient the masses on the shaft in such a way that center of mass = $\sum m_1 r_1 = 0$
- d) For that randomly orient masses m_1 and m_2 (i.e.2) and then analytically solve for getting orientation of 3 and 4 (i.e. 4).
- e) Manually orient m_3 and m_4 at calculated angles '4' and then see if there is an unbalance, there will be most probably.
- f) You then need to finely adjust the orientations of any two masses to make the system statically stable.

Need of balancing:

If the pulleys are not properly balanced, it results in the increasing the loads on bearings and also produce vibrations. To minimise the pressure on bearings, balancing is necessary.

Benefits of balancing:

- · Free from noise
- Free from vibrations
- · Improved bearing life
- Improved shaft life as well as protection from bending by eliminating cantilever effect
- Improved belt life
- Safety: unbalanced pulleys running on higher R.P.M. can even breaks into pieces which can cause for major accident / damage.

Static balancing: One-Plane Balancing (DIN-2211 part 1)

Static balancing is adopted for the pulleys where peripheral speed is less than 20 m/s. If the pulley is not balanced, the shaft will turn until the heavier side is on the bottom. A hole is bored until the pulley is in static balance, or remains mobile regardless of what position it is placed in.

Pulley balancing

Dynamic balancing:

Dynamic balancing is necessary when

- Surface speed is greater than 30 m/s and large diameter Pulleys.
- Ratio of Pulley diameter to Pulley face width d: w < 4
- Dynamic or two plane balancing:
- Balance corrections are made and measured at 2 planes on the component axis.
- Non balanced units of masses are spread along the length of the component.

Dynamic or two plane balancing (As per DIN-2211 part 1)

A two-plane balance is recommended only in certain cases where the product face width is relatively large and the operational speed relatively fast, or where balance is considered very critical.

Pulley alignment inspection

Misalignment can either be quantified mathematically, or be compared to some general rules of thumb for quicker and easier results. While using a straight edge to project the plane of the outside face of the sheave or sprocket #1 with respect to sheave or sprocket #2, angular misalignment can be quantified as the difference in clearance between the straight edge and the outside surface of the sheave or sprocket #2 across the diameter.

The angle of parallel misalignment can be quantified as the difference in clearance between the straight edge and the outer surfaces of the two sheaves or sprockets across the separation distance.

Pulley alignment inspection

The total allowable misalignment recommended for V-Belts, in general, is 1/2-degree. While individual V-Belts are known to be capable of handling greater amounts of misalignment before becoming unstable, maintaining the misalignment to within 1/2-degree will maximize Belt life.

The total amount of misalignment recommended for synchronous, banded Belts and poly-V Belts is 1/4-degree. These drives are less tolerant of misalignment than conventional V-Belt drives, and must be aligned more accurately.

For V-Belt drives:

1/2-degree angle = approximately 1/10-inch per foot of distance traveled. For synchronous, 60-degree angle, and V-ribbed drives:

Installation of taper bush pulley

Caution: Switch off the power supply before commencing work on electrical components.

Step 1:

Make sure the bush is taken out of the hub if it's already installed. Clean the taper bush thoroughly, remove oil, dirt, grease, and metal filings.

Also clean the bore, the shaft, the outer surface of the bush.

Step 2:

Put the bush within the hub and align with the half threaded holes of pulley with those of the un-threaded half holes of bush to fix the position.

Step 3:

Lubricate inserting tip and threads of the set screws. Put the screws in the holes that are threaded hub-side. Tighten the set screws manually in alternate pattern till possible rotations.

Step 4: Put the assembly onto the shaft and keep it in the right position. Insert the right sized key into the shaft keyway and ensure that the key is the most suitable fit into the shaft keyway. Further tighten the alternate set screws until every screw is pulled up and the bushing has been perfectly placed into the hub.

Step 6: Run the drive under load for short time and re-check tightness of screws, if loosen; tighten for specified tightening torque.

Step 7: Fill the other holes with grease to Restrict foreign particle contamination.

Disassembling the Taper Bush Pulley:

Step 1:

Take out the set screws from taper bush pulley.

Step 2: Put screws into the holes threaded on the bushing part. Skip one screw that is not used while removing the bushing.

Step 3: Tighten the placed screws until the bushing gets to loosen up in the hub. In case it's not loosening instantly, tap on the hub (use Wooden /Teflon hammer) to help it remove.

Step 4: Remove the pulley, including the bush, from shaft

Types of Pulleys

V-Pulleys

Poly-V Pulleys

Timing Pulleys

Sheet metal Pulleys

Self cooling Pulleys

QD Bush Pulleys

Non-standard Pulleys

Service Equipment

PIX-Service Kit

PIX Service Kit is a composite gear with all essential tools required by the users in maintaining the drive.

PIX-X'Align (Laser-guided Pulley Alignment Instrument)

Robust and highly effective maintenance tool, used to correct the misalignment of pulleys in a drive.

PIX-Digital Tension Meter

PIX Digital Tension Meter is used to correct the tension factor in a drive, thus helping the users' to attain the optimum Belt-tension.

PIX-Pulley Gauges

PIX-Pulley Gauges are specially designed for checking the profiles of the grooves of various conventional and dual-section pulleys.

PIX at a Glance...

- Fastest emerging global player in the mechanical power transmission products
- Over five decades of expertise of manufacturing quality products
- Strong global brand identity
- Distribution network in over 100 countries
- Global product approvals, quality management systems
- · Global presence, subsidiary operations in U.K., Germany and UAE
- State-of-art infrastructure for the development, manufacturing and testing of products
- Dedicated and committed R&D team
